Current evidence

- Ivermectin is a broad spectrum antiparasitic drug with known antiviral properties.
- On April 3, 2020, Caly et al. published evidence from in vitro experiments showing that ivermectin can inhibit the replication of SARS-CoV-2 at micromolar concentrations.

ABSTRACT

Although several clinical trials are now underway to test possible therapies, the worldwide response to the COVID-19 outbreak has been largely limited to monitoring/containment. We report here that Ivermectin, an FDA-approved anti-parasitic previously shown to have broad-spectrum anti-viral activity *in vitro*, is an inhibitor of the causative virus (SARS-CoV-2), with a single addition to Vero-hSLAM cells 2 h post infection with SARS-CoV-2 able to effect ~5000-fold reduction in viral RNA at 48 h. Ivermectin therefore warrants further investigation for possible benefits in humans.

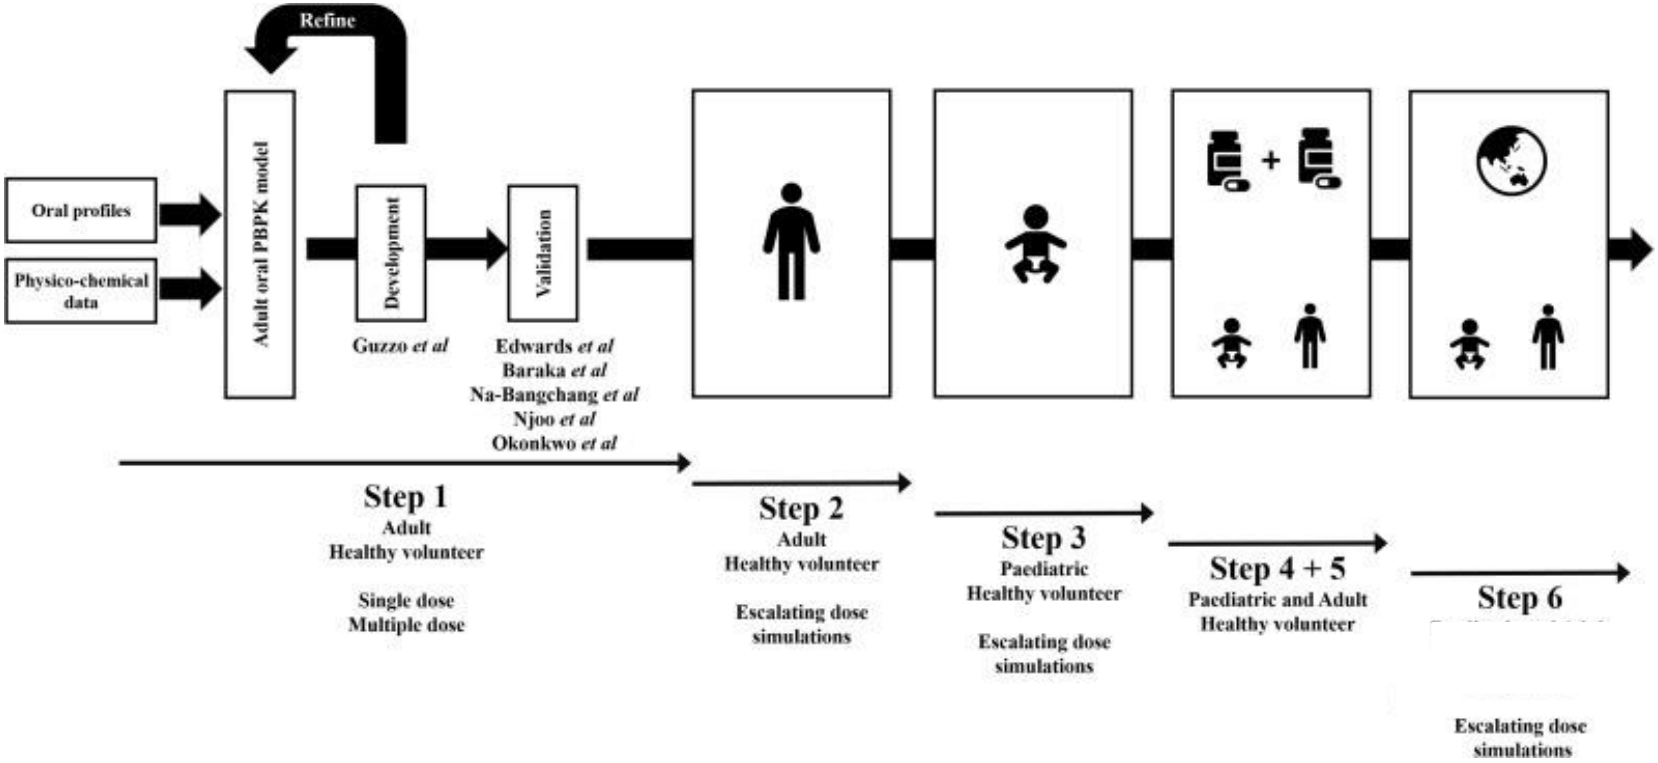
- Vero/hSLAM cells were infected with SARS-CoV-2 isolate Australia/VIC01/ 2020 at an MOI of 0.1 for 2 h, followed by the addition of 5 µM ivermectin.
- At 24 h, there was a 93% reduction in viral RNA present in the supernatant (indicative of released virions) of samples treated with ivermectin compared to the vehicle DMSO.
- Similarly a 99.8% reduction in cell-associated viral RNA (indicative of unreleased and unpackaged virions) was observed with ivermectin treatment.
- By 48 h this effect increased to an ~5000-fold reduction of viral RNA in ivermectin-treated compared to control samples, indicating that ivermectin treatment resulted in the effective loss of essentially all viral material by 48 h.
- Consistent with this idea, no further reduction in viral RNA was observed at 72 h.

L. Caly, J.D. Druce, M.G. Catton, D.A. Jans, K.M. Wagstaff, The FDA-approved drug ivermectin inhibits the replication of SARS-CoV-2 in vitro, Antiviral research (2020) 104787.

Current evidence (2)

- This discovery gave hope to the researchers who are screening for drugs that can be repurposed for treating the Coronavirus Disease 2019 (COVID-19).
- This has torn the scientific community into two opposing views, one group calling for avoiding investment and effort in a drug likely to fail clinical trials, and another group calling for rapid scale-up even in the absence of proven safety and efficacy for the potential COVID-19 indication.
- Since April 2020, there has been an abundance of observational trials, case series and ecological analyses suggesting a potential efficacy of ivermectin against COVID-19.
- Yet very few reports of rigorously conducted randomized controlled clinical trials.

Ivermectin – Repurposed?



Sharun *et al. Ann Clin Microbiol Antimicrob (2020) 19:23* https://doi.org/10.1186/s12941-020-00368-w

Ivermectin – Repurposed?

- Ivermectin, is a member of the avermectin family; as these compounds are produced by the soil microorganism, *Streptomyces avermitilis,* they are called avermectins.
- Ivermectin has showed a wide range of activities, ranging from broad-spectrum endo/ecto-parasiticide activity to antiviral, antibacterial, and anticancer activities.
- It was first introduced commercially in 1981 for use in animals. In addition to being used for treating billions of livestock and companion animals worldwide to help maintain food production and animal health, ivermectin is also used for treating several diseases in humans, e.g. a key drug in the elimination programs of onchocercosis.
- Ivermectin is considered a drug of choice for various parasitic diseases. As an anthelmintic drug, its mechanism of action in invertebrates mainly involves the opening of glutamate-gated and Gamma aminobutyric acid (GABA)-gated chloride channels, leading to increased conductance of chloride ions and causing subsequent motor paralysis in parasites

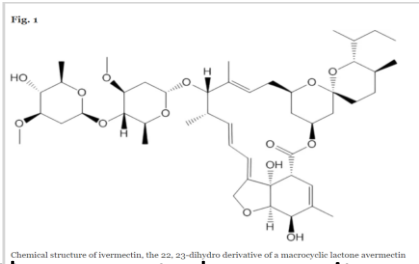
Sharun *et al. Ann Clin Microbiol Antimicrob (2020) 19:23* https://doi.org/10.1186/s12941-020-00368-w

Ivermectin – Drug Properties

Ivermectin is a broad-spectrum highly lipophilic anti-parasite medication.

A small molecule with a group of pentacyclic sixteen-membered lactone (i.e. a macrocyclic lactone disaccharide).

Primarily hepatic metabolism, and/or its metabolites are excreted almost exclusively in the faeces over an estimated 12 days, with less than 1 % of the administered dose excreted in the urine.



Despite this it is moderately well absorbed better absorbed with a high fat meal

The volume of distribution is 3 to 3.5 L/kg and it does not cross the blood-brain barrier.

For the treatment of intestinal (i.e., nondisseminated) strongyloidiasis due to the nematode parasite Strongyloides stercoralis. Also for the treatment of onchocerciasis (river blindness) due to the nematode parasite Onchocerca volvulus. Can be used to treat scabies caused by Sarcoptes scabiei, and other associated conditions such as Acne Rosacea, Ascaris lumbricoides infection, Cutaneous larva migrans, Demodicidosis, Gnathostomiasis, Mansonella ozzardi infection and others.

Sharun *et al. Ann Clin Microbiol Antimicrob (2020) 19:23* https://doi.org/10.1186/s12941-020-00368-w

Ivermectin – Mechanism of Action

- Agonist for the inhibitory neurotransmitter gamma-aminobutyric acid (GABA) and can be administered orally, topically or by injection
- Binding GABA-gated chloride and invertebrate-specific glutamate-gated anion channels in peripheral neuromuscular synapses, suppressing nerve impulse conduction
- Its usefulness as an anthelminthic results from differences in the distribution of GABA receptors between mammals and arthropods or nematodes: GABA receptors in mammals are mostly in the central nervous system (CNS) protected by the blood brain barrier, whereas in arthropods and nematodes they are found in the peripheral nervous system at the neuromuscular junction.
- Stimulation of GABA receptors in endo- and ecto-parasites causes flaccid paralysis and inhibits feeding of the parasite

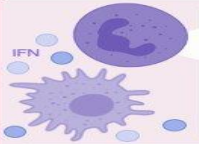
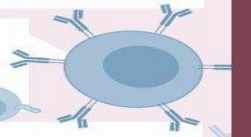
Immune Response



Innate Immune Response
- Delayed or suppressed Type I Interferon (IFN) response during initial infection
- Viral replication triggers hyperinflammatory conditions and cytokine storm
- Influx of activated neutrophils and inflammatory monocytes/macrophages
- Serum neutrophilia and elevated pro-inflammatory cytokines are associated with severity of disease



Adaptive Immune Response
- T helper cells Th1/Th17 are engaged
- IgM and IgG are usually detectable within two weeks after infection
- Lymphopenia may be related to bone marrow suppression

Laboratory Findings

Mild disease	Lymphopenia (most common finding), leukopenia, ↑CRP
Moderate to severe disease	↑AST, ↑ALT, ↑CK, ↑D-dimer, ↑ferritin, ↑LDH

SARS-CoV-2

The protein ACE -2 expresses in high quantities in the respiratory epithelia, allows for viral entry and infection of the lung and alveolar cells

ACE-2 enzyme expression is important for blood pressure regulation and interferon production

SARS-CoV-2 binding to these receptors impedes these processes

It was known to inhibit the nuclear import of viral and host proteins.

Integrase protein of viruses and the importin (IMP) α/β1 heterodimer was responsible for IN nuclear import which further increases the infection

As most of the RNA viruses are dependent upon IMPα/β1 during infection, Ivermectin acts on it and inhibits the import with the increase in antiviral response

CD147 along with ACE-2 has been recognized as a key binding site for SARS-CoV-2 spike protein. Ivermectin shields SARS-CoV-2 spike protein which binds to CD147 and ACE-2.

Abstract:

Coronavirus disease (COVID-19) remains a world pandemic with little treatment options. Nature has provided a plethora of compounds that may offer potential protection and/or treatment choices. Earlier studies have shown a pivotal role of Angiotensin converting enzyme 2 (ACE2) in the pathogenesis of COVID-19. In this context, seven natural compounds were selected and their binding to specific peptide sequences of the coronavirus S-protein: ACE2 interface-drug binding adduct were calculated. Further to the natural drugs, we also similarly examined four well-known antiviral drugs. Moreover, the binding-interface of the isolated coronavirus S-protein and the isolated ACE2 receptor were also individually explored. The identified drug molecules positioned itself achieving geometries of minimum energy resulting in limiting viral recognition of host cells or to disturb host-virus interactions. The frontier orbitals (HOMO-LUMO) play crucial role in the binding interactions of the studied molecules. Most of the drugs act as electron sink whereas the S protein behaves as nucleophile. The results reported pave the way for the identification of small-drug molecule of natural origin with potentially tolerable side effects that can offer protection and/or treatment against coronavirus S-protein COVID-19. Experimental validation is of urgent demand.

4- Conclusions

11 ligands (7 natural and 4 synthesized antivirals) were calculated to bind to either the S-protein: ACE2 interface-ligand binding complex or the binding-interface of the isolated S-protein, ACE2, Heme or Heparin. We showed that the identified drugs could be positioned to limit viral recognition of host cells or disturb host-virus. Simplified assumptions of Frontier orbitals interactions are successful in explaining the results. Generally, in presence of ACE2 enzyme, drugs act as Lewis acids (or electron sink molecules) towards the viral S protein that exhibits strong electrophilic property. Hydroxychloroquine, ivermectin and favipiravir are strongest binding drugs to both S protein and ACE2, while raspberry-ketone, menthol, eriodictyol and thymoquinone are potentially bind to S protein. Raspberry-ketone is of comparable binding strength to hydroxychloroquine and ivermectin antiviral drugs, which are currently clinically investigated. Moreover, raspberry ketone seems to block or at least disturb S protein – ACE2 interactions. Other natural drugs did not show affinity to bind to either S protein or ACE2. However, they disturb direct S protein – ACE2 interaction by showing capabilities to receive electrons (electron sink) into its disturbed LUMO from S protein in presence of ACE2. Thymoquinone is the only drug among the tested ones that showed electron acceptor capability towards heme.

ABSTRACT

Although several clinical trials are now underway to test possible therapies, the worldwide response to the COVID-19 outbreak has been largely limited to monitoring/containment. We report here that Ivermectin, an FDA-approved anti-parasitic previously shown to have broad-spectrum anti-viral activity *in vitro*, is an inhibitor of the causative virus (SARS-CoV-2), with a single addition to Vero-hSLAM cells 2 h post infection with SARS-CoV-2 able to effect ~5000-fold reduction in viral RNA at 48 h. Ivermectin therefore warrants further investigation for possible benefits in humans.

Caly et al. showed that when 5 μM of ivermectin was added to Vero/hSLAM cells with SARS-CoV-2 isolate Australia/VIC01/2020, viral RNA in the supernatant (indicated virions that were released) was reduced by 93% and RNA of virus associated with cell was reduced by 99.8% (indicated virions that were not released and packaged). Furthermore, it was stated that by 48 h ivermectin brought about 5000 fold reduction of viral RNA and the IC50 was found out to be ~2 μM [2].

https://www.clinicaltrials.gov/

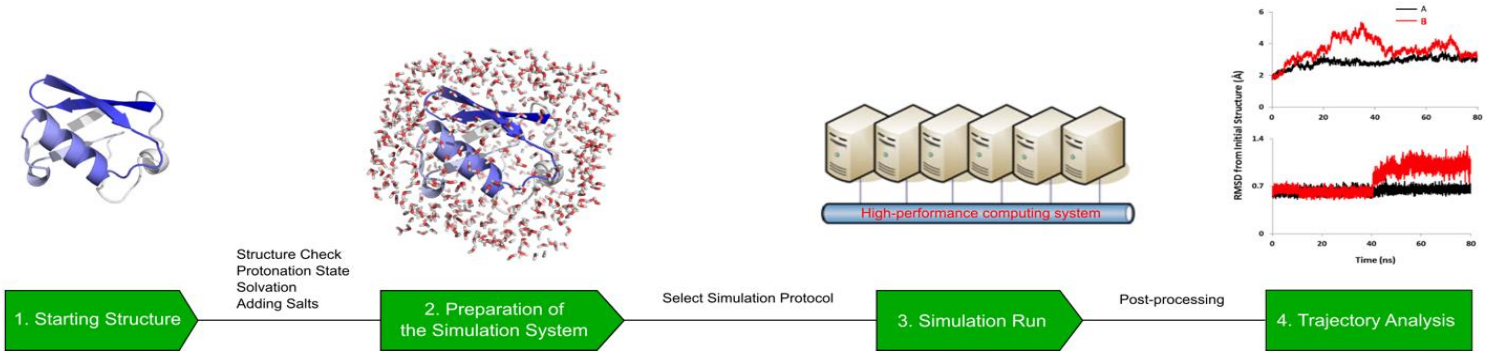
Clinical Studies - Summary

- Some beneficial results have been observed with these studies
- However
  - 12 RCTs were included in the final analysis heterogenous in nature (disease states, populations and controls)
  - most of these studies have been conducted in mild to moderate diseases therefore greater diligence and regulatory review is required for testing of ivermectin in sever conditions
  - Ivermectin targets the invertebrate's glutamate gated chloride channels, and can also cross-target mammalian GABA-gated chloride channels in the CNS
  - In normal conditions, this is prevented by the BBB BUT in individuals having hyperinflammatory states endothelial permeability at BBB may be enhanced leading to drug leakage into the CNS and neurotoxicity
  - ARVs like lopinavir/ritonavir and darunavir inhibit cytochrome P450 3A4 (main metabolic pathway for Ivermectin) if used concurrently can increase systemic exposure to ivermectin. Ritonavir inhibits P-glycoprotein efflux pump in BBB.
  - DOSING – population pharmacokinetic studies (dosed at 200 μg/kg, 60 mg, and 120 mg) after administration of single and repeat fasted dose for total and unbound plasma concentration- time profiles. Indicated that the IC50 value of ivermectin as reported by Caly et al. was much higher than the maximum plasma concentration achieved after administration of the above mentioned three doses when administered fasted. Thus the likelihood of success in a clinical trail at the approved dose of 200 μg/kg is less. A similar study indicated that the excessive dosages used in vitro is not feasible in vitro.
  - TARGET- IVM is HIGHLY protein bound (93 %) making highly unlikely that their will be adequate endothelial uptake
  - TOTAL LUNG CONCENTRATION – animal studies indicate that when 200 μg/kg were injected only 100 ng/g (around 0.1 μM) in the lung tissue of calves – thus at normal conventional dosages one would not achieve therapeutic levels.

Molecular dynamics simulations based studies

- The binding coordinates of ivermectin observed were at the prime regions crucial for the activity of particular SARSCoV proteins. The least structural deviation with the nucleocapsid protein N terminal domain (1.89 Å±0.33) and high interaction ratio points toward the suggestion that ivermectin exhibits relatively high afnity for N protein. The nucleocapsid shuttling has been proposed to be facilitated via human Importin α/β into the nuclear matrix.

- The reported binding of ivermectin to importin α/β and notably low infection in ivermectin treated patients, might also possibly suggest that there is noticeable binding with the nucleocapsid cargo itself.



Kaur et al, Ivermectin as a potential drug for treatment of COVID-19: an in sync review with clinical and computational attributes – Pharmacological reports, 2021

What about prophylaxis?

Many studies, only two individual RCTs - included both treatment and prevention groups and has only been reported in pre-print. No detail was provided in the preprint about the baseline characteristics of the trial participants or the time from exposure to receiving ivermectin as prophylaxis.

Challenge with prophylactic dosing - Ivermectin has a plasma half-life of ≈16 to 18hrs with time-length ranging from 4 to 12days. Thus Ivermectin given 1x/month you wouldn't have effective drug in your system after 12 days. This makes a 1x/month dosing scheme pharmacologically irrelevant for the finding

Ivermectin in the treatment of COVID-19— friend or foe?

The global number of deaths due to COVID-19 is almost at the two million mark, with over 35 000 deaths in South Africa. Although there are hopes of a safe and effective vaccination programme, the increasing number of COVID-19 cases in the country is putting a significant strain on the healthcare system. Ivermectin, an antiparasitic drug, has been widely published on social media platforms and news outlets as a so-called miracle drug for the treatment of COVID-19. Ivermectin is not registered in SA as a drug for human use, but rather as a veterinary and agricultural product. Currently, from a small number of randomised controlled trials (RCTs), there does seem to be a signal of evidence for the use of ivermectin in the management of COVID-19. Pharmacists must, however, remain cognisant of their ethical responsibilities as well as the applicable regulations that prohibit the procurement and dispensing of any unregistered medicine.

Keywords: COVID-19, SARS-CoV-2, ivermectin, avermectin, macrocyclic lactone, endectocide

Ivermectin is not currently registered in South Africa, but may be obtained on a named-patient basis with the approval of the local regulatory body, the South African Health Products Regulatory Authority (SAHPRA).[15] Ivermectin has been described as a so-called wonder drug and excitement around repurposing this

In South Africa..

The evidence for the use of ivermectin in COVID-19 has been reviewed by the South African National Department of Health (SA-NDoH), SAHPRA, and the MAC on COVID-19, and the following conclusions were made:[23,26,27]

Until more robust evidence is available, the routine use of ivermectin for either the prevention or treatment of COVID-19 is not justified.

Nonetheless, emerging evidence must be actively sought and carefully reviewed. Reports of clinical trials of ivermectin for the prevention or treatment of COVID-19 must be closely watched, as they become available. As always, reports in peer-reviewed publications will be preferred.

Concluding statements

- Despite nearly 30 years of use in veterinary and human medicine there is much to learn about IVM
- The clinical efficacy and utility of IVM in SARS CoV-2 infected patients are unpredictable at the moment as this is a completely novel virus
- The possible signal of efficacy found with IVM warrants robust larger trials of IVM in SARS CoV-2
- There should be better and more effective communication with the public

Thank You
